

## 32-bit MCU with 14-bit ADC, 6 PGA's, 2 Buck DC/DC, integrated 3-phase Pre-Drivers with supply up to 96V

Revision A/0 – October 2022

### Features

- 32-bit ARM Cortex-M4 CPU Core with FPU
  - 200MHz maximum frequency
- Memories
  - 128 KB embedded flash
  - 512 bytes OTP flash
  - 64 KB on-chip SRAM
- Power Management
  - Integrated Buck DC/DC for pre-driver supply
  - Integrated Buck DC/DC for 3.3V supply
- Pre-Driver Module
  - 3-Phase Pre-Driver for BLDC motor control application with 96V max input voltage
  - Integrated bootstrap diodes
  - Integrated charge pump for 100% duty cycle
  - 2A and 1A pull-up and pull-down options
  - Programmable output swing from 8V to 18V
  - Six external power FET  $V_{DS}$  monitors
- Clock, reset and supply management
  - Brown-out Detect (BOD) on each power rail
  - Power-On Reset (POR)
  - 1 to 66 MHz external crystal oscillator
  - 32 MHz factory-trimmed RC oscillator
  - PLL for CPU clock
  - Typical 2.2MHz safety clock
- 14-bit A/D converters (up to 8 channels)
  - As low as 140 ns conversion time
  - Conversion range: 0 to 3.65 V
  - Differential sampler
  - Triple-sample and hold capability
  - Open/short detection for safety
  - Temperature sensor
- Programmable gain amplifier (PGA)
  - Three integrated PGAs in MCU
  - Programmable Gains  
Single-ended: 1,2,4,8,12,16,24,32  
Differential: 2,4,8,16,24,32,48,64
  - Typical 400 ns settling time
- Motor PGA
  - Three differential PGAs with negative input voltage capability in Pre-Driver
  - Programmable Gains  
Differential: 2, 4, 8, 12, 16, 32, 64
  - Typical 400 ns settling time
- Analog comparator
  - Ten high-speed comparators
  - Output with digital deglitch filter
  - 4 DACs as reference
  - Optional DAC output buffer
  - Out of range voltage protection
  - Phase comparison
- PWM
  - Six enhanced PWM modules
  - 12 PWM outputs in total
  - Signal generation with phase lead/lag control
  - All events can trigger ADC conversion
- Up to 19 GPIO Pins
  - Configurable pull-up/pull-down resistors
  - Programmable digital input deglitch filter

QFN40 (6 x 6 mm, 0.5mm pitch)  
QFN56 (7 x 7 mm, 0.4mm pitch)

- Enhanced Capture Module (ECAP)
  - Flexible input capture pin
  - Four 32-bit capture registers
  - Capture and PWM mode selection
- Debug mode
  - Serial wire debug (SWD) & JTAG interfaces
- 6 Timers
  - Three 32-bit general-purpose timers
  - Two 32-bit watchdog timers
  - SysTick timer 24-bit down-counter
- Communication interfaces
  - UART x 1, SPI x 1, I<sup>2</sup>C x 1, SIO x 1
  - SIO can be configured as CAN, SPI, UART, I2C, etc.
- Deep sleep mode with off current as low as 15uA
- Security Modules
  - CRC x 1, AES x 1, 64-bit unique ID
- Operating temperature
  - Junction temperature: -40 to +125 °C
  - Ambient temperature: -40 to +105 °C

# 1 Device overview

SPD1188 is a SiP (System in a Package) device integrating MCU, Pre-Driver module and power management module to have “all-in-one” chip for BLDC motor driving application with supply voltage up to 96V.

The MCU incorporates a 32-bit ARM Cortex-M4 high-performance processor with a software-programmable clock rate as high as 200 MHz, 64 KB SRAM, embedded flash with 128 KB, and an extensive range of enhanced I/Os and peripherals. The device offers a 14-bit ADC, six PGAs, six enhanced PWMs, three general purpose 32-bit timers, as well as standard and advanced communication interface: an UART, an I<sup>2</sup>C and a SPI. These features make the SPD1188 ideal for motor control application.

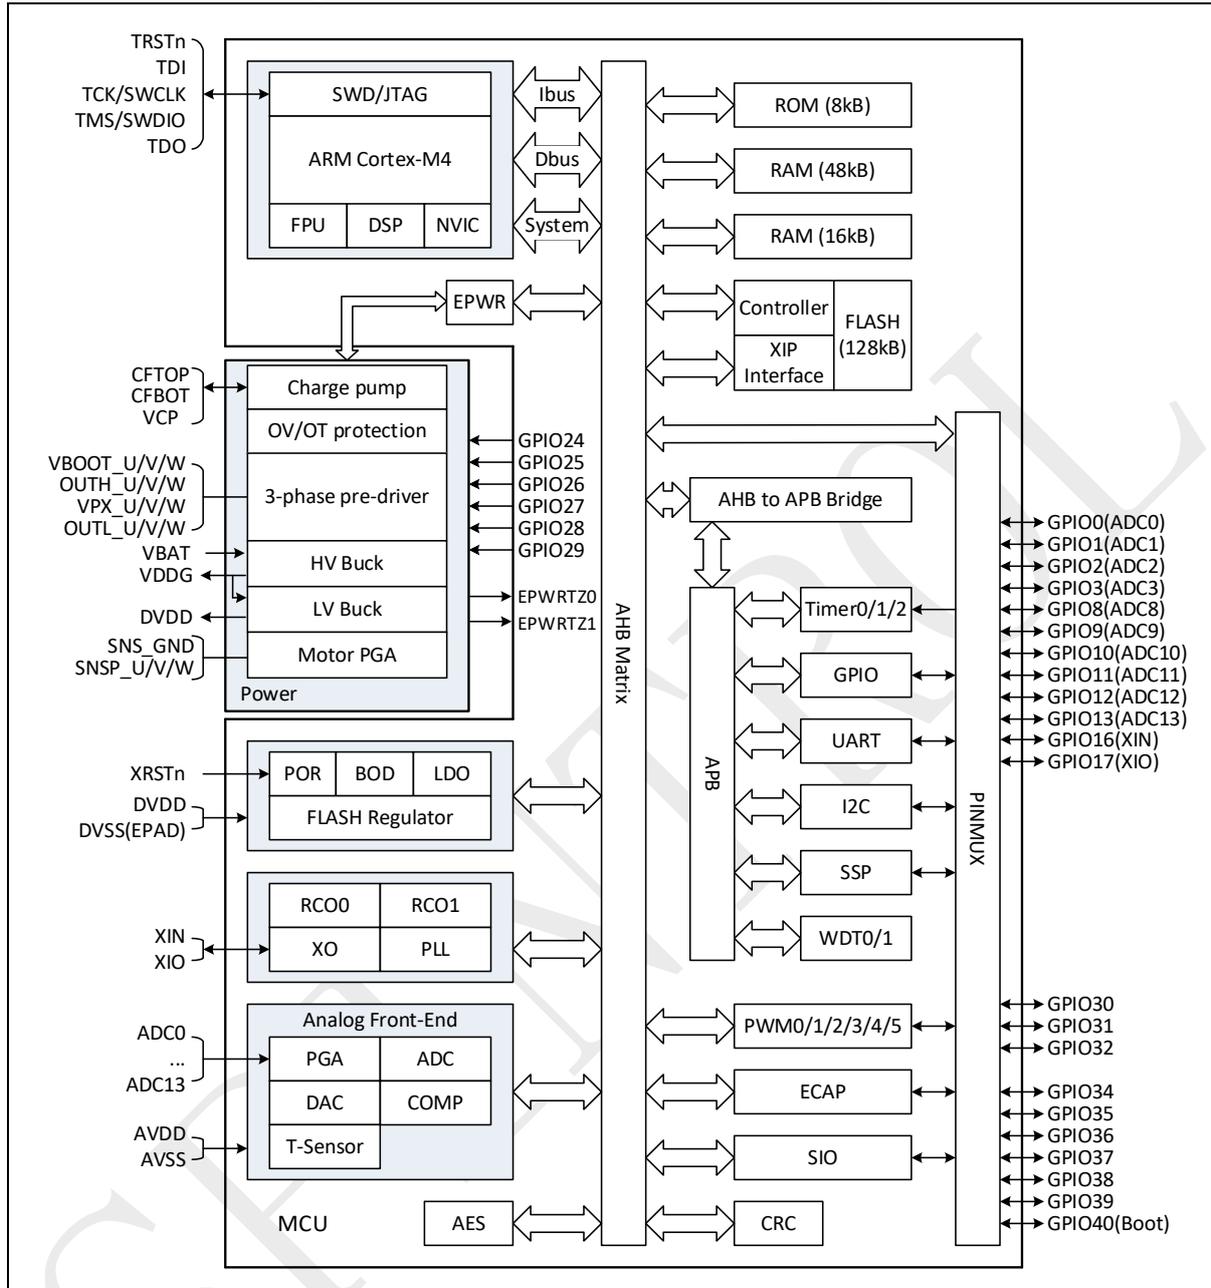

The Pre-Driver module provides three half-bridge pre-drivers, with programmable charging/discharging current capability up to 2A. Integrated Charge Pump supports 100% duty cycle.

The Power management module includes a 96V Max input, 12V 300mA output synchronous HV buck, a 12V input, 3.3V 500mA output synchronous LV buck, and Brown-out-Detection observing each of the power rail.

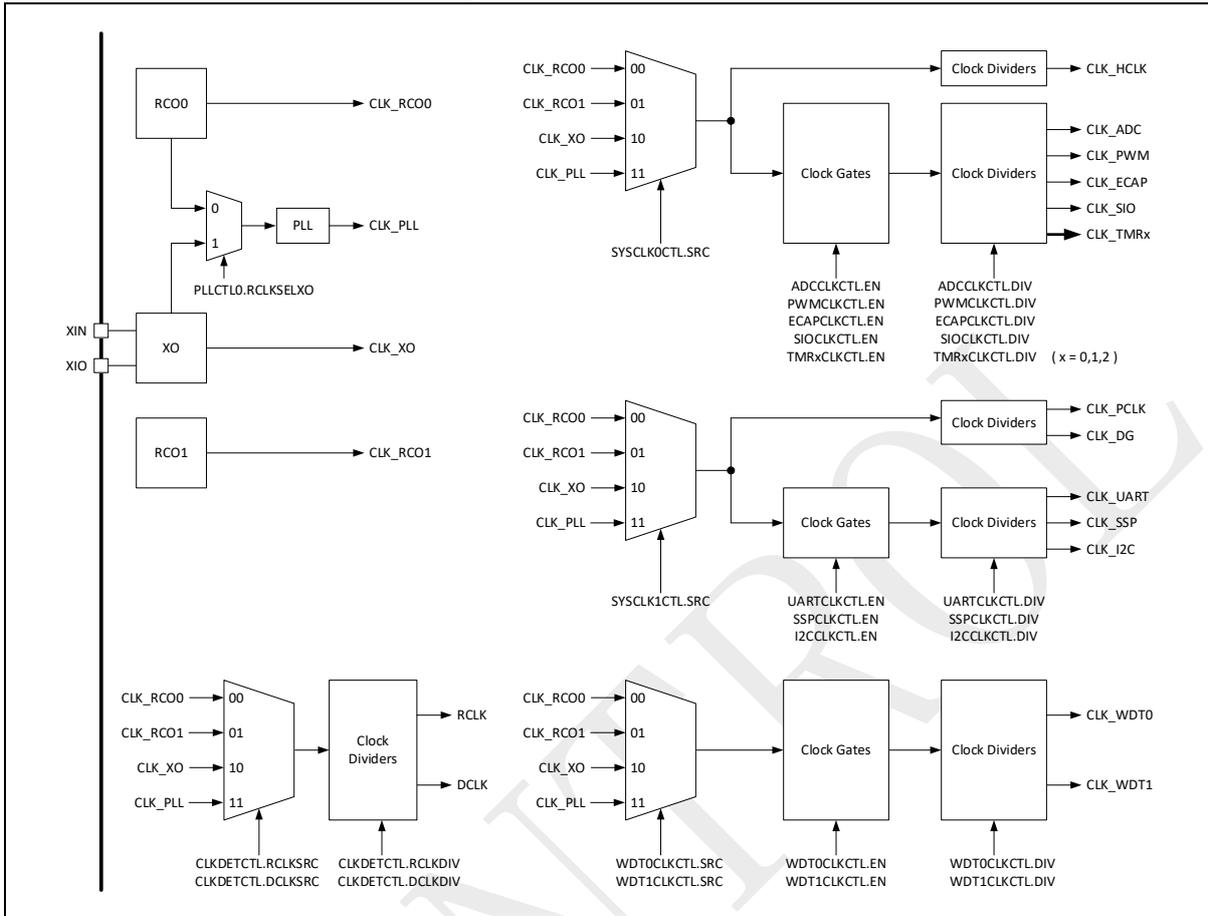

The temperature range is from -40 °C to +125 °C. The package type is 56-pin or 40-pin QFN.

[Figure 1-1](#) shows the functional block diagram for the SPD1188. [Figure 1-2](#) shows the clock tree information. The physical connection scheme between the MCU and the high voltage power module is show in [Figure 1-3](#). The typical application diagram is shown in [Figure 1-4](#).

## 2 Feature descriptions

### 2.1 ARM Cortex-M4 core

The ARM Cortex-M4 processor has been developed to provide a low-cost platform that meets the needs of MCU implementation, with a reduced pin count and low-power consumption, while delivering outstanding computational performance and an advanced system response to interrupts.

The SPD1188 integrates a full-feature ARM Cortex-M4 core with FPU that can run up to 200MHz. Therefore, it is compatible with all ARM tools and software.

### 2.2 Embedded SRAM

The SPD1188 has implemented 64 KB SRAM memory for code and data. The SRAM can be accessed (read/write) at CPU clock speed with 0 wait states.

### 2.3 Embedded Flash memory

Up to 128 KB of embedded Flash memory is available for storing programs and data.

### 2.4 Nested vectored interrupt controller (NVIC)

The SPD1188 embeds a nested vectored interrupt controller able to handle up to 51 maskable interrupt channels (not including the 16 interrupt lines of Cortex-M4) and 16 programmable priority levels.

- Closely coupled NVIC gives low-latency interrupt processing
- Interrupt entry vector table address passed directly to the core
- Processing of *late arriving* higher priority interrupts
- Support for tail-chaining
- Support for lazy-stacking
- Interrupt entry restored on interrupt exit with no instruction overhead

### 2.5 External interrupt/event controller

The SPD1188 provides a flexible external pin interrupt or event trigger mechanism. Any GPIO pin can be programmed as an external interrupt or event trigger source. In addition, any GPIO interrupt can be configured as edge-triggered or level-triggered.

## 2.6 Power supply, reset and deep sleep mode

The SPD1188 requires a single 8V to 96V power supply. All derivative supplies such as low-side pre-driver supply, main digital MCU 3.3V supply, MCU 1.2V supply are generated on-chip from a single input supply. External generation option for derivative supplies is also available.

The SPD1188 has a global reset pin as well as an integrated power-on reset (POR) circuitry. The POR circuitry guarantees all power-up reset sequence requirements and makes the device easy to use.

Deep sleep mode option is provided, during which, both HV buck and LV buck will be disabled and all the control blocks are disabled except reset monitoring logics used to wait for wake-up command. So, the turn off current can be as low as 15uA.

## 2.7 Brown-out detector

The device features an embedded brown-out detector (BOD) that monitors the main input supply  $V_{BAT}$ , low-side pre-driver supply  $V_{DDG}$ , main digital MCU 3.3V supply  $V_{DD}$  and MCU 1.2V supply voltage levels and compare them to the programmable pre-set values. An interrupt or reset can be generated when voltage of any of the power domains is higher or lower their respective pre-set values. The interrupt service routine will then generate a warning message and/or put the MCU into a safe state. The BOD is enabled by software. The MCU BOD for 3.3/1.2V supplies is implemented inside the MCU, separately from high-voltage BOD system.

## 2.8 Clocks

The MCU system clock selection is performed on startup. The internal 32 MHz RC oscillator is selected by default upon reset. An external 1 – 66 MHz oscillator can be selected by the user.

The device implements a fractional phase-lock loop (PLL) for high frequency clock generation. The PLL can take the internal RC oscillator or external clock as the input reference clock. The output frequency covers range from 25MHz to 200MHz.

Several clock dividers allow the configuration of the AHB, APB and the peripherals frequency. The maximum allowed frequency is 200MHz for AHB and 50 MHz for APB. See [Figure 1-2](#) for details on the clock tree. Special clock selection logic is designed so that the backup clock can take charge if current clock is missing. The 2.2MHz backup-safety oscillator makes the SPD1188 get rid of clock stuck.

## 2.9 Boot mode

The boot code is located in on-chip ROM memory. After reset, the ARM processor starts code execution from the ROM. The boot pin and TRSTn pin are used to select one of the two boot options:

- Boot from embedded Flash (boot pin = 1, TRSTn pin = X): the boot loader jumps to the

embedded Flash and runs from the address at 0x1000 0000

- ISP mode (boot pin = 0, TRSTn pin = 0): the boot loader reprograms the embedded Flash by using UART. During the process, the GPIO34 is configured as UART\_TXD and the GPIO35 is configured as UART\_RXD.

*Note 1: The boot pin should always keep high when chip normally running.*

*Note 2: The TRSTn pin is recommended to set as low.*

*Note 3: When TRSTn is high, the related debug interface pins (GPIO36 ~ GPIO39) must not be used as GPIO function.*

## 2.10 General-purpose IOs (GPIOs)

The SPD1188 can be configured to support as many as 19 multi-purpose GPIO pins. Each GPIO pin can be configured by software as input, as output or as peripheral alternate function. It features:

- Each GPIO pin has configurable internal pull-up and pull-down resistors
- Each GPIO pin has a programmable digital input deglitch filter

## 2.11 Timers and watchdogs

The SPD1188 device includes three general-purpose timers, two watchdog timers and a SysTick timer.

### General-purpose timers

The SPD1188 includes three identical 32-bit general-purpose timers. Each general-purpose timer consists of a 32-bit auto-reload down-counter. An interrupt would be generated when the counter reaches zero if it is enabled. When the counter reaches zero, the timer can also generate an ADCSOC event or a PWMSYNC event if they are enabled. The clock of general-purpose timer can be selected from internal RC oscillators, external oscillator or PLL clock. Besides, each general-purpose timer can also capture external input as timer clock or enable signal.

### Watchdogs

The SPD1188 implements two identical watchdogs. Each watchdog is based on a 32-bit down-counter, which can be clocked from internal RC oscillators, external oscillator or PLL clock. When the counter reaches the given time-out value, an interrupt or a reset can be generated. The watchdog counter can be frozen or free-running in debug mode.

### SysTick Timer

This timer is dedicated for OS, but could also be used as a standard down-counter. It features:

- A 24-bit down-counter
- Auto-reload capability
- Mask-able system interrupt generation when the counter reaches 0

## 2.12 UART

The SPD1188 has an UART module that are functionally compatible with the 16550A and 16750 industry standards. It features:

- Ability to add or delete standard asynchronous communication bits (start, stop and parity) in the serial data
- 5 – 8 data bits
- Even, odd or no parity detection
- One, one-and-a-half, or two stop bits generation
- Baud-rate generation up to 12.5 Mbps
- 64-byte transmit FIFO
- 64-byte receive FIFO
- Auto baud-rate detection

## 2.13 I<sup>2</sup>C

The I<sup>2</sup>C bus interface complies with the common I<sup>2</sup>C protocol and can operate in standard mode (with data rates up to 100 Kb/s) and fast mode (with data rates up to 400 Kb/s). It features:

- Three speeds: Standard mode (100 Kb/s), Fast mode (400 Kb/s) and High-Speed mode (2 Mb/s)
- Clock synchronization
- Master or slave I<sup>2</sup>C operation
- 7- or 10-bit addressing
- 7- or 10-bit combined format transfers
- 16 x 32-bit deep transmit and receive buffers, respectively

## 2.14 SPI

The SPI allows half/full-duplex, synchronous, serial communication with external devices. It features:

- Full-duplex synchronous transfers
- Master or slave operation
- 1 to 32-bit transfer frame format selection
- 50 Mbps maximum communication speed
- MSB-first data order
- Programmable clock polarity and phase
- Transmit and receive FIFOs

## 2.15 ADC

A 14-bit analog-to-digital converter is embedded into SPD1188 and has up to 8 external channels. In addition, the temperature sensor, internal powers and PGA outputs can be

selected as ADC input channels. These inputs are multiplexed internally. The ADC core has three independent built-in sample-and-hold (S/H) blocks. Each S/H has two input channels, which is suitable for differential sampling.

The events generated by the general-purpose timers and the PWM outputs can be internally connected to the ADC start trigger.

- 14-bit resolution
- 140 ns minimum conversion time and independent configurable sampling time
- Differential sampling
- Triple-sample and hold capability
- Simultaneous sampling and sequential sampling modes supported
- Full range analog input: 0 V to 3.65 V
- Reference voltage can be selected from internal or external source
- ADC external channel input open and short detection for safety

Please see [Table 5-12](#) for ADC characteristics.

## 2.16 Temperature sensor

The temperature sensor generates a voltage that varies linearly with temperature. It is internally connected to the ADC input channel, which is used to convert the sensor output voltage into a digital value.

## 2.17 PGAs

Three flexible programmable gain amplifiers (PGAs) are embedded into MCU portion of SPD1188 and share up to 8 input channels. The temperature sensor and internal 1.2V power can be selected as a PGA input channels. These inputs are multiplexed. Each PGA outputs are connected to ADC input channel.

- Programmable gains for general purpose PGAs  
Differential mode: 2, 4, 8, 16, 24, 32, 48, 64; Single-ended mode: 1, 2, 4, 8, 12, 16, 24, 32.
- Differential mode optimized for motor current sensing using on-board resistive level shifters  
Settling time: 400 ns to 800 ns

Please see [Table 5-13](#) for on-MCU PGA characteristics.

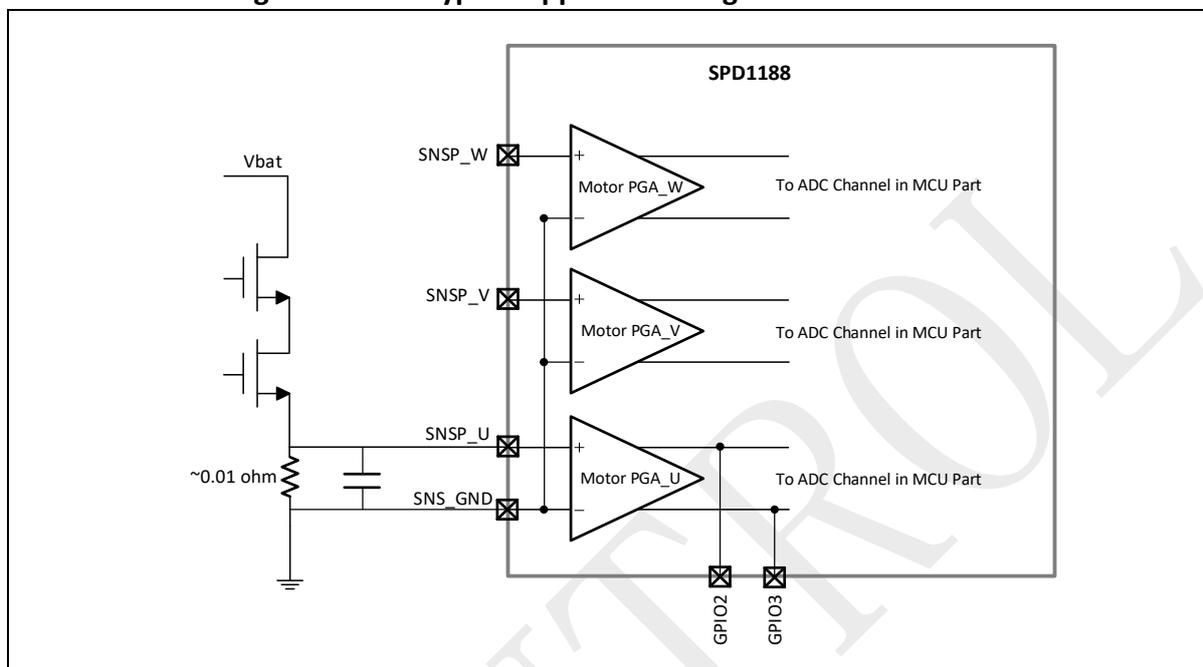

## 2.18 Motor PGAs

Additionally, three fully differential PGA's are provided in SPD1188 Pre-Driver module. These PGA's common mode voltage can be close to GND and thus suitable for direct motor current sensing without on-board resistive level shifter. [Figure 2-1](#) shows the typical application diagram for motor PGA. Programmable gain is realized by selecting different feedback resistor  $R_f$ . The connection relationship between Motor PGA and ADC channel is shown in [Figure 1-3](#). **Due to the design scheme, when motor PGA is used, GPIO2 and GPIO3 has to be floating.**

- Programmable gains for Motor PGAs  
Differential mode: 2, 4, 8, 12, 16, 32, 64

Please see [Table 5-14](#) for Motor PGA characteristics.

**Figure 2-1. Typical application diagram for Motor PGA**

## 2.19 Analog comparators

The SPD1188 has ten high-speed comparators. Each comparator uses the internal DAC as reference for monitoring PGA inputs or outputs. Two comparators are designed for each PGA: one is monitoring whether the voltage is too high, the other is monitoring whether the voltage is too low. The extra two pairs of comparators are reserved for additional applications. The comparator output is routed to the PWM Trip-Zone modules. Additionally, each comparator can implement the phase comparison for motor commutation. The detail channel selection can be referred to Technical Reference Manual.

- 50 ns typical response
- Programmable hysteresis
- Output with digital deglitch filter
- Phase comparison

Please see [Table 5-15](#) and [Table 5-16](#) for analog comparator and DAC characteristics.

## 2.20 PWMs

The SPD1188 integrates six PWM modules and supports 12 PWM channels. Without much involvement of processor core, the PWMs can generate complex pulse width waveforms.

Each PWM module supports the following features:

- Dedicated 16-bit time-base counter with period and frequency control

- Each PWM module can generate two outputs with single-edge operation, dual-edge symmetric operation or dual-edge asymmetric operation
- All events can trigger both CPU interrupts and ADC start of conversion
- Programmable phase-control support for lag or lead operation relative to other PWM modules
- Dead-band generation with independent rising and falling edge delay control
- Programmable trip zone allocation of both cycle-by-cycle trip and one-shot trip on fault conditions
- A trip condition can force either high, low, or high-impedance state logic levels at PWM outputs
- Comparator module outputs and trip zone inputs can generate events, filtered events, or trip conditions

## 2.21 ECAP

The enhanced capture (ECAP) module is essential in systems where accurate timing of external events is important. The SPD1188 has implemented an ECAP module with following features:

- Flexible input capture pin: each GPIO can be configured as capture pin
- 32-bit time base counter
- 4 x 32-bit time-stamp capture registers
- 4-stage sequencer that is synchronized to external events
- Independent edge polarity (rising/falling edge) selection for all 4 events
- Interrupt capabilities on any of the 4 capture events

## 2.22 Cyclic redundancy check (CRC)

The SPD1188 has a hardware CRC calculation unit. The CRC module is used to verify data transmission or storage integrity. It features:

- 32-bit parallel bit stream input, and up to 32-bit CRC output
- Supports up to  $2^{32}$  byte length for CRC calculation
- Five CRC standard polynomials supported

## 2.23 Advanced encryption standard (AES) engine

The AES engine provides fast hardware encryption and decryption services. The main features are as follows:

- Supports as many as six block cipher modes: ECB, CBC, CTR, CCM\*, MMO, and Bypass
- Supports 128-, 192-, and 256-bits key size
- Error indication for each block cipher mode
- Separate 4 x 32-bit input and output FIFOs

## 2.24 Serial wire JTAG debug port (SWJ-DP)

The ARM SWJ-DP interface is embedded and is a combined JTAG and serial wire debug port. The SWJ-DP interface enables either a serial wire debug or a JTAG probe to be connected to the target. The debug port can be disabled when enabling SPD1188 certain security feature.

## 2.25 SIO

SPD1188 has implemented an SIO module, which is based on a Spintrol patented technology. It has programmable capability that can convert the SIO module into pre-defined communication module. Currently the SIO can be used as UART, SPI, I2C and CAN once it is programmed through initialization. There will be more features added in short time.

## 2.26 Power management module

SPD1188 integrates power management module including HV Buck, LV Buck providing 10V and 3.3V power rail respectively.

HV buck converts main input supply  $V_{BAT}$  to  $V_{DDG}$  rail, which is typically 10V for defining pre-driver output voltage swing. HV buck uses synchronous rectification with no external power FET or diode. On-board compensation network is needed and the values of each passive component are shown in the typical application diagram in [Figure 1-4](#). HV buck will start operating when  $V_{BAT}$  voltage is higher than 8.15V and shut down when  $V_{BAT}$  voltage drops below 7.65V. Typical switching frequency for HV buck is 600 kHz, and typical current limit value is 300mA.

LV buck converts  $V_{DDG}$  to DVDD rail, which is typically 3.3V for powering MCU. LV buck uses synchronous rectification with no external power FET or diode. No compensation network is needed. Inductor value is 10uH and output cap is 10uF as shown in the typical application diagram in [Figure 1-4](#). LV buck will start operating when  $V_{DDG}$  voltage is higher than 6.5V and shut down when  $V_{DDG}$  voltage drops below 6.2V. During power up, it will wait for HV buck to finish soft start, typically 1ms, before start operating. Typical switching frequency for LV buck is 1.2MHz, and typical current limit value is 600mA.

## 2.27 Pre-Driver system

Pre-driver system consists of a three low- and high-side pre-drivers which can drive the three phases of low- and high-side external power NFET's or IGBT's. The voltage range of each low-side pre-driver is zero to  $V_{DDG}$ , which is typically 10V. The embedded charge pump guarantees 100% duty cycle, i.e. allows high-side of each phase to be on indefinitely without loss of charge on the high-side pre-driver stage. Non-overlap time is built in to prevent high side and low side power FET to turn on at the same time even in case of overlapping input PWM command. VDS monitor is used to observe the Drain to Source voltage of the turned-on external power FET and compare it to pre-set programmable reference. When excessive current flows

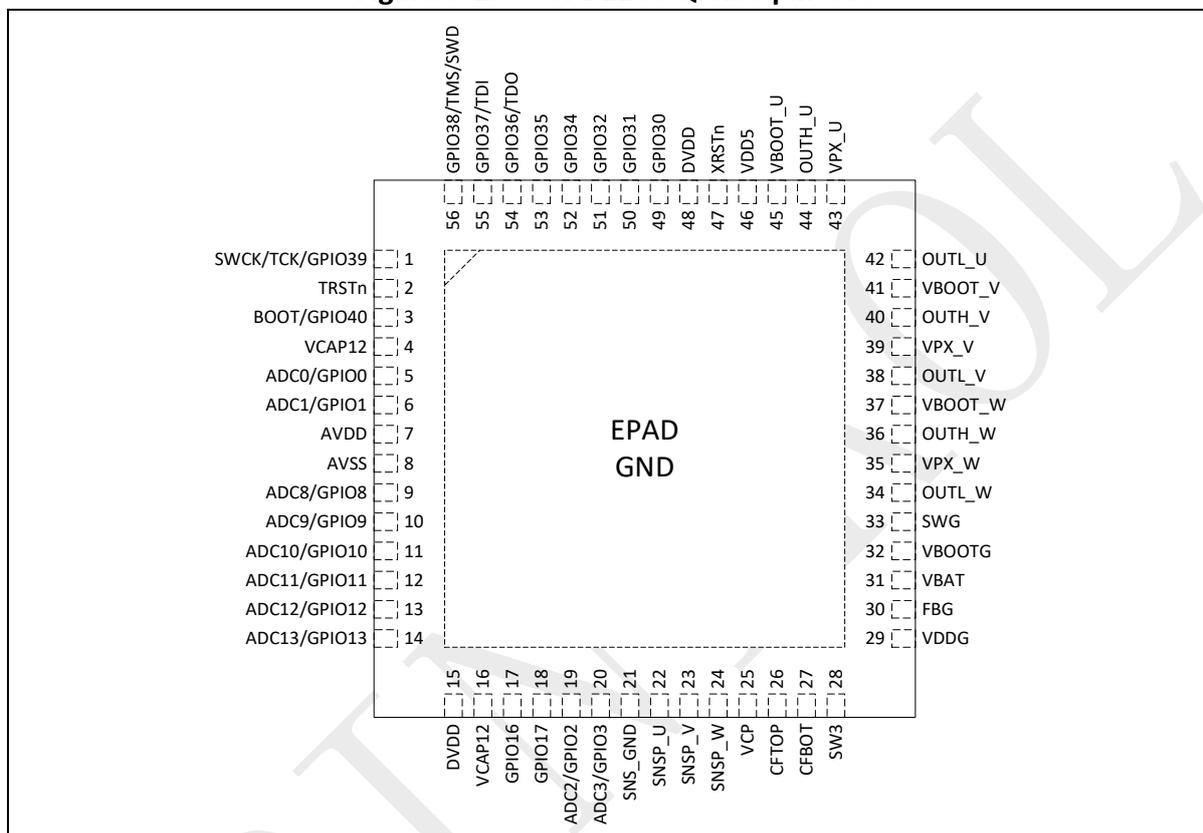

through the power FET, fault will be trigger to stop the Motor PWM signal through PWM trip zone.

### 3.3 PGA input channel selection

For the three on-MCU PGA's, each PGA has two 1-of-8 multiplexers (MUX) for input channel selection, one is for positive input (PGA<sub>x</sub>\_P, x = 0,1,2) and the other is for negative input (PGA<sub>x</sub>\_N, x = 0,1,2). The input channel selection table is shown below.

**Table 3-3: PGA input channel selection**

## 5.4 Power consumption summary

### Typical current consumption

In operational mode, the SPD1188 is placed under the following conditions:

- All I/O pins are in input mode and left unconnected;
- All peripherals (including analog module) are enabled, except SIO module;
- All peripheral clocks are as fast as HCLK (frequency division is Zero), except SSP (Max 50 MHz) I2C (Max 50 MHz), PCLK (Max 50 MHz);
- All clock modules are enabled;
- Select PLL clock as system clock source.

In idle mode, the SPD1188 is placed under the following conditions:

- All I/O pins are in input mode and left unconnected;
- All peripherals (including analog module) are clocked off or disabled;
- Clock modules (PLL, RCO0 and XO) are disabled;
- Select RCO1 as system clock source.

In global deep sleep mode, the SPD1188 is placed under the following conditions:

- Both HV buck and LV buck will be disabled thus no power supply for MCU and pre-driver
- All the control blocks are disabled except reset monitoring logics used to wait for wake-up command.

In MCU-only deep sleep mode, the SPD1188 is placed under the following conditions:

- LV and HV Buck's are on;
- All I/O pins are in input mode and left unconnected;
- All peripherals (including analog module) are clocked off or disabled;
- Clock modules (PLL, RCO1 and XO) are disabled;
- 1.2V LDO is shut down to 0V.

The typical current consumption of SPD1188 measured from VBAT is shown in [Table 5-4](#) and [Table 5-5](#). The operational current consumption over various HCLK frequency is shown in [Figure 5-1](#).

## On-chip peripheral current consumption

The current consumption of the on-chip peripherals is given in [Table 5-6](#). The MCU is placed under the following conditions:

- All I/O pins are in input mode and left unconnected;
- All peripherals(including analog module, RCO0 and XO) are disabled unless otherwise mentioned;
- The given value is calculated by measuring the current consumption
  - With all peripherals clocked disabled
  - With only one peripheral enabled

**Table 5-6: Peripheral current consumption**

Peripherals <sup>[1]</sup>		Conditions	Typ <sup>[2]</sup>	Unit	
BOD		Select RCO0 as system clock source; All other peripherals are in default settings; Close PLL, XO, RCO1 and RCO0 after disabling or enabling BOD module	0.1	mA	
ADC	Analog <sup>[3]</sup>	Select PLL clock as system clock source; All peripheral clocks are as fast as HCLK; $f_{HCLK} = 128 \text{ MHz}$ , $f_{PCLK} = 32 \text{ MHz}$ , $f_{PLL} = 128 \text{ MHz}$	16.52	mA	
	Digital		0.31	mA	
T-Sensor			0.16	mA	
PGA <sup>[4]</sup>			4.10	mA	
DAC			0.18	mA	
Comparator			0.08	mA	
UART			UART clock 200MHz, 256000 bps	0.416	mA
I2C			I2C clock 50MHz, 3.4Mbps	0.316	mA
SSP		SSP clock 50MHz, 50Mbps	0.361	mA	
PWM		PWM clock 200MHz	1.471	mA	
ECAP		ECAP clock 200MHz	0.329	mA	
WDT		WDT clock 200MHz	0.245	mA	
TMR		TMR clock 200MHz	0.385	mA	
SIO		SIO clock 100MHz	6.63	mA	
FLASH		HCLK clock 200MHz	0.772	mA	
XO		HCLK is from 200MHz PLL, which takes RCO0 as input	0.616	mA	
RCO		HCLK is from 200MHz PLL, which takes XO as input	0.313	mA	
PLL		XO as HCLK source, $f_{PLL} = 32 \text{ MHz}$	1.153	mA	

[1] For peripherals with multiple instances, the current quoted is for single modules. For example, the 4.10 mA value quoted for PGA is for one PGA module. So the total 3 PGA module current is 12.30mA.

[2] Typical values are measured at  $T_A = 25 \text{ }^\circ\text{C}$ ,  $V_{DD} = 3.3 \text{ V}$ .

[3] ADC analog current contain ADC analog module, bandgap and ADC reference buffer.

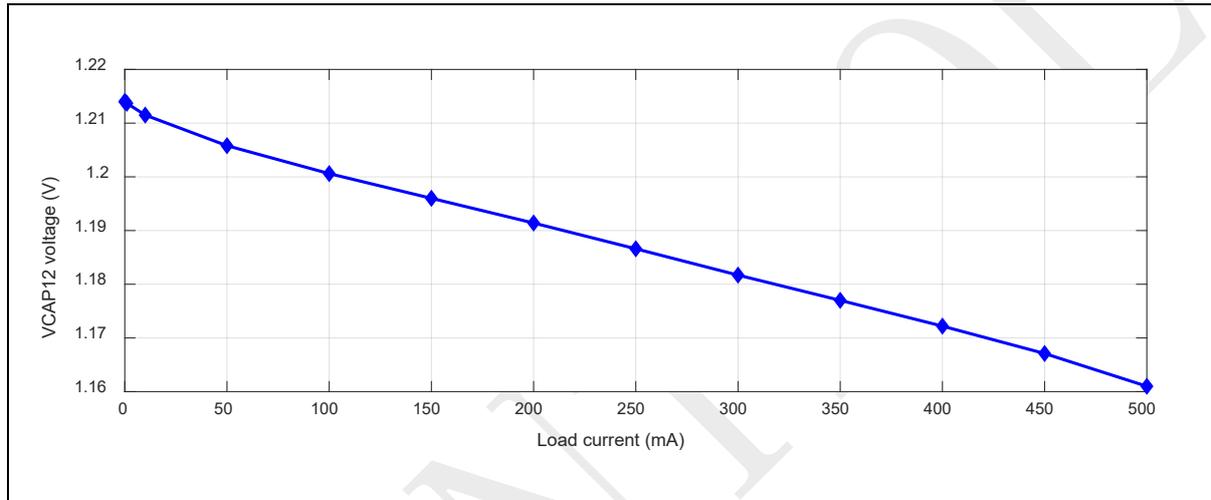

[4] The Bandgap must be enabled when enabling ADC (Analog Part), T-sensor, PGA, DAC and comparator.

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
V <sub>VDDG_Max</sub>	Max operating voltage	-	-	-	20	V
V <sub>VDDG_UV_Trigger</sub>	Under voltage trigger threshold	-	-	6.2	-	V
V <sub>VDDG_UV_Release</sub>	Under voltage release threshold	-	-	6.5	-	V
DVDD	3.3V output	-	3.14	3.3	3.47	V
R <sub>ON_HS</sub>	High side Ron	300mA	-	1.1	-	Ω
R <sub>ON_LS</sub>	Low side Ron	300mA	-	0.4	-	Ω
I <sub>Limit</sub>	Valley current limit	-	-	600	-	mA
η	Power efficiency	V <sub>BAT</sub> = 12V, 200mA, 1.2MHz	-	90	-	%

## 6 PCB layout guidance

- Connect low-ESR bypass capacitors from  $V_{BAT}$ ,  $V_{DDG}$ ,  $DVDD$ ,  $V_{DD5}$ ,  $VCAP12$ ,  $VCP$  to ground, placing capacitors as close as possible to their respective pins, with the other end of each capacitor having a strong connection to board ground.
- Enough through holes should be put under the chip EPAD for a good connection to the copper ground plate. This is essential for thermal dissipation.
- Put ceramic 10nF the bootstrap cap between  $VBOOTG$  and SWG pin as close to the chip as possible.
- For both HV buck and LV buck, output capacitor should be put close to the inductor, and the ground connection should be tied to IC ground  $VSS$  through short trace or copper plate.
- Co-locate power FET pairs with drain of low-side adjacent to source of high-side to minimize both  $L_{sh}$  and  $L_{dl}$ , and pairs placed close to each other to reduce routing distance and minimize  $L_r$  and  $L_d$ .
- Use thick, direct tracks between FET's with no loops or deviation.
- Minimize the areas of major current paths shown by arrows in the diagram of [Figure 6-1](#) to avoid any loops.
- In case of standing power FET's, reduce the effect of lead inductances by lowering package height above PCB.
- Connect the other end of  $C_0$  (shown in [Figure 6-1](#)) as close as possible to the drain of high-side FET, in order to provide the lowest-parasitic return path for current.
- Place IC closer to power switches; route gate driver control signals  $OUTH$  and  $OUTL$ , and high- and low-side return grounds  $VPX$  and  $GND$  with straight as-short-as-possible traces.
- Connect bootstrap capacitor as close as possible to  $VPX$  and  $VBOOT$  pins.
- Use power FET's with fast body diode turn-on times and as small as possible diode reverse charges.
- $DVDD$  is the feedback of buck DCDC, in order to keep the stable operation of control loop, it is recommended to keep  $DVDD$  trace away from high voltage switching trace and noisy source, such as inductor, etc.
- Keep the switching trace as short and wide as practical in order to minimize radiated emissions.
- The  $GND$  trace between the  $DVDD$  capacitor and the  $GND$  pin should be as wide as possible so that trace impedance is minimized.
